

**FRV Walther Herwig III
Cruise 377
28.08. – 17.09.2014**

Integrated Monitoring of Contaminants and their Biological Effects (INMON)

NATO project MODUM

Scientist in Charge: Dr. Thomas Lang

Summary

As part of the integrated monitoring programme of the Thünen Institute of Fisheries Ecology (FI) on contaminants and biological effects (incl. fish diseases) in fish from the North Sea and Baltic Sea, studies were carried out in eight Baltic Sea and seven North Sea areas. In addition to the onboard examination of dab (*Limanda limanda*), flounder (*Platichthys flesus*) and cod (*Gadus morhua*) for externally visible diseases and parasites, a large range of fish samples were taken for a subsequent analysis of contaminants and their biological effects. As part of the NATO-funded MODUM project (2013-2016), extensive studies were carried out on the health status of cod in dumping areas for chemical munitions and reference areas. Samples of diverse fish species were frozen for studies on radionuclides and for contaminant analyses in the framework of national and international marine monitoring programmes (BLMP, OSPAR, HELCOM). Hydrographical measurements were carried out (water temperature, salinity, oxygen content, turbidity). The following preliminary findings were noted:

Dab: No new trends of disease prevalence in the North Sea and Baltic Sea; as in 2013, increasing prevalence of some diseases on a north-westerly transect in the German North Sea EEZ from the inner German Bight to the Dogger Bank;

Flounder: no new trends regarding disease prevalence;

Baltic cod: Again, low prevalence of acute/healing skin ulcerations and skeletal deformities; nematodes in the body cavity in all Baltic Sea areas, especially in sampling areas east of Bornholm; Increase in prevalence of *Loma morhua* (= *branchialis*) in the gills, but very likely due to the application of more accurate examination procedures; cod east of Bornholm were characterized by a markedly lower condition factor than cod west of Bornholm.

Participants:

Name	Function	Institution
Dr. Thomas Lang	Scientist in Charge	TI-FI Cuxhaven
Jennifer Ipse	Technician	TI-FI Cuxhaven
Alexander Schulz	Technician	TI-FI Hamburg
Jan Neukirchen	Scientist	TI-FI Hamburg
Dr. Marc-Oliver Aust	Scientist	TI-FI Hamburg
Dr. Victoria Magath	Scientist	TI-FI Hamburg
Horst Bahl	Scientist	TI-FI Hamburg
Lina Weirup	Student	University Hamburg
Kolja Franssen	Student	University Hamburg
Christoph Rummel	Volunteer	University Mainz
Shauna Grassmann	Volunteer	University Göttingen
Bianca Haas	Volunteer	University Graz

Objectives of the Cruise

1. Studies on fish diseases and parasites in the North Sea and Baltic Sea;
2. Studies on biological effects of contaminants;
3. Studies for the MODUM project;
4. Sampling of fish for chemical analysis of contaminants;
5. Hydrographical measurements (salinity, temperature, oxygen, turbidity).

Dates of the Cruise

FRV Walther Herwig III left Bremerhaven in the early afternoon of 28.08. and sailed to the first sampling area in the North Sea, where work started in the morning of 29.08. in area GB1. After the passage of Kiel Channel, technical problems had to be fixed in Kiel. In the afternoon of 31.08., work started in the Baltic Sea in area B01 (Kiel Bight). The next morning, a member of the scientific staff was taken on board from FRV Clupea off Saßnitz and work was resumed in area B11. In the following days, sampling was conducted in areas BHB, B09, B15, B14, B13, B10 and B01. In the evening of 08.09., after the end of the Baltic Sea programme, Walther Herwig III arrived in Kiel due to the need for medical treatment of a crew member.

On 09.09., WHIII again passed Kiel Channel. In the period 10.-15.09., sampling was continued in five North Sea areas (N01, GB4, P02, N06, N04, GB3). In the evening of 16.09., WH III arrived in Bremerhaven, where the cruise ended in the morning of 17.09. according to schedule.

The location of the sampling areas and the cruise dates are shown in Fig. 1 and 2 and Tab. 1. In 15 sampling areas (Fig. 1), a total of 59 fishing hauls was performed (towing time 30–60 min. each) (geographical coordinates in Tab. 1, catch composition in Tab. 2). In the Baltic Sea, a 140 ft bottom trawl and a pelagic PSN 205 net were used, in the North Sea a GOV net, all with standard configuration. Hydrographical measurements were made at all fishery stations (geographical coordinates in Tab. 1a, results in Tab. 3).

Preliminary Results

1 Dab (*Limanda limanda*)

In total, 4,919 dab (total length \geq 10 cm below) from one Baltic Sea and six North Sea areas were examined for the occurrence of externally visible diseases and parasites (Tab. 4) and 641 dab (total length \geq 20 cm below) for the occurrence of liver anomalies (Tab. 5).

The prevalence of some diseases in the North Sea was comparable with those from previous cruises in 2013. The prevalence of lymphocystis was in range of 0.3 - 16.9 %, with the lowest value in the inner German Bight (area GB1) und the highest values off the Scottish coast (area N06). The prevalence of epidermal hyperplasia/papilloma was in the range of 0.5 % (inner German Bight, area GB1) to 4.6% (south-eastern Dogger Bank, area GB4). Marked regional variation was again recorded for hyperpigmentation, with values between 6.0 % (inner German Bight, area GB1) to 58.0 % (south-eastern Dogger Bank, area GB4). The strongest regional differences were noted for the parasite *Stephanostomum baccatum* (juvenile digenetic trematode under the skin), the prevalence of which ranged from 2.4 % (inner German Bight, area GB1) to 99.5 % (Ekofisk, area P02).

For the majority of diseases, there was a prevalence gradient – as during the previous cruises in 2013 - in the German EEZ in north-westerly direction, with increasing values from the inner German Bight (area GB1) to the south-eastern Dogger Bank (area GB4) (see Fig. 3. and Tab. 4). When interpreting this finding, it has to be taken into account that the mean size of the dab examined increased in north-westerly direction, too, possibly affecting the prevalence, but not exclusively responsible for the gradient recorded.

The prevalence of liver nodules >2 mm (= tumours and pre-stages) was low and comparable to values recorded during previous cruises in 2013. For dab of the size range 20-24 cm total length, the prevalence was in the range of 0.0 % (inner German Bight, area GB1) to 9.1 % (south-eastern

Dogger Bank, area GB4), for dab of the size group ≥ 25 cm the prevalence ranged from 0.0 % (Scottish coast, area N06) to 28.0 % (Dogger Bank, area N04).

Baltic Sea dab from Kiel Bight (area B01) displayed differences in disease prevalence to the North Sea dab especially for hyperpigmentation and the parasites *Stephanostomum baccatum*, *Acanthochondria cornuta* (copepode on the gills) and *Lepeophtheirus pectoralis* (copepode on the skin and under the pectoral fins). These diseases/parasites are extremely rare in the Baltic Sea. The prevalence of the other diseases recorded does not differ from the North Sea in contrast.

2 Flounder (*Platichthys flesus*)

1,099 flounder from six Baltic Sea areas and one of the North Sea areas (inner German Bight, area GB1) were examined for the occurrence of externally visible diseases and parasites (Tab. 6). The prevalence of lymphocystis in the Arkona Sea was low compared to the previous cruise in winter 2013 (WH 370, 30.11.-20.12.2013) (area B10: 15.8 %; area B11: 15.6 %). For *Lepeophtheirus pectoralis*, the marked regional pattern previously known was confirmed. A high prevalence occurred in the inner German Bight (90.6 %; area GB1, North Sea) and Kiel Bight (42.6 %; area B01, Baltic Sea), whereas flounder from all other areas were not affected.

3 Cod (*Gadus morhua*)

In total, 3,986 cod from eight Baltic Sea areas and one North Sea area were examined for externally visible diseases and parasites and for nematodes in the body cavity (Tab. 7). The disease prevalence was low in general, and for acute/healing stages it ranged from 0.0 % (Kiel Bight, area B01) to 10.2 % (Arkona Sea, area B11). Skeletal deformities were rare, too, with maximum values of 2.7 % (in Gdansk Deep, area B15). The prevalence of the gill parasite *Loma morhua* (= *branchialis*) was higher compared to previous cruises; very likely due to the application of improved and more accurate examination techniques. Larval nematodes in the body cavity were recorded in cod from all Baltic Sea areas, with the highest prevalence in the sampling areas east of Bornholm (exception: Kiel Bight, area B01). It is not yet clear if this infestation is linked to the bad fitness of the eastern cod (fishes are lean and have low condition factors; see Fig. 3). Markedly lower condition factors were recorded in cod from the major dumpsite for chemical warfare agents in the Bornholm Basin (area B13).

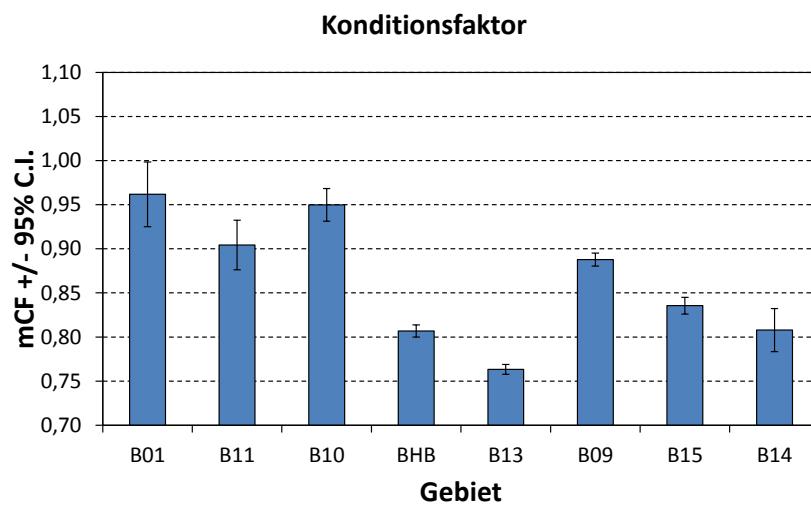

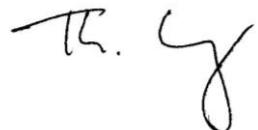

Fig. 3: Cruise 377 RV 'Walther Herwig III', 28.08. - 17.09.2014:
Mean condition factors of cod (with 95 % confidence intervals)
($CF = [\text{total weight}/\text{length}^3] * 100$)

4 Miscellaneous

The mean catch data of the most frequent fish species are provided in Tab. 2; Tab. 3 gives results of the hydrographical measurements.

Acknowledgements

Thanks are due to Captain Vandrei and his crew and to the scientific staff for constructive and hard work and a very good atmosphere on board.

A handwritten signature consisting of the letters "T" and "L" followed by a stylized "y".
